INTRODUCTION

This article contains notes from the course *Computational Commutative Algebra and Algebraic Geometry* taught by Professor Michael Stillman in Winter 2025 as part of the Fields Academy Shared Graduate Courses program. It contains formal definitions for mathematical concepts related to rings. It uses Z Notation[3] and has been type checked by fUZZ [4].

0.1. Source Material. The course is concerned with Computational Commutative Algebra and Algebraic Geometry. The course uses `Macaulay2` for computation. I'll use [1] as the source for Commutative Algebra and [2] as the source for Algebraic Geometry.

0.2. Type Checking. I'll start by pulling in the set of real numbers \mathbb{R} , and its zero element 0. So far, these are just \LaTeX commands.

Next, I'll say something formal about them.

Remark. *Zero is a real number.*

$0 \in \mathbb{R}$

0.3. **TODO List.** Define enough terms so that I can express the problem sets. Also try to write formal specifications for the data types and functions in `Macaulay2`.

Define the following terms:

- ring
- homomorphism
- ideal
- field
- quotient of ring modulo an ideal
- ideal quotient, colon ideal
- Hilbert series, function
- monomial order
- Gröbner basis
- elimination as in `Macaulay2`

1. RINGS AND IDEALS

Refer to [1, Chapter 1] for definitions.

1.1. **Rings and Ring Homomorphisms.** A *ring* A is a set with addition and multiplication operations such that:

- (1) The set A is an abelian group with respect to addition. The zero element is denoted by 0 and the additive inverse of $x \in A$ is denoted by $-x$.
- (2) Multiplication is associative ($(xy)z = x(yz)$) and distributive over addition ($x(y + z) = xy + xz, (y + z)x = yx + zx$).
- (3) The ring is said to be *commutative* if the multiplication is commutative.
- (4) The ring is said to have an *identity element* if it has an element that is a left and right multiplicative identity

1.1.1. *Rings.* The first two axioms define a general ring. Regarded as a structure, define a ring \mathbf{A} to be a triple $(A, (-+), (- * -))$ consisting of a set, an addition operation, and a multiplication operation.

$Rng_Core[t]$ $A : \mathbb{P} t$ $- + -, - * - : pbin_op[t]$ $\mathbf{A} : \mathbb{P} t \times pbin_op[t] \times pbin_op[t]$
$(A, (- + -)) \in abgroup[A]$ $(A, (- * -)) \in semigroup[A]$ $\forall x, y, z : A \bullet x * (y + z) = (x * y) + (x * z)$ $\forall x, y, z : A \bullet (y + z) * x = (y * x) + (z * x)$ $\mathbf{A} = (A, (- + -), (- * -))$

- addition is an abelian group
- multiplication is a semigroup
- left multiplication distributes over addition
- right multiplication distributes over addition
- the structure is a triple consisting of the carrier and two operations

Here I have omitted the letter i in the name Rng to remind us that a general ring is not required to have a multiplicative identity element.

The additive identity element is denoted 0 , the additive inverse of x is denoted $-x$, and the sum of x and $-y$ is denoted $x - y$.

$Rng[t]$ $Rng_Core[t]$ $0 : t$ $- : t \rightarrow t$ $- - - : pbin_op[t]$
$0 = identity_element(A, (- + -))$ $(\lambda x : A \bullet -x) = inverse_operation(A, (- + -))$ $(- - -) = (\lambda x, y : A \bullet x + (-y))$

- 0 is the additive identity element
- $-x$ is the additive inverse of x
- subtraction is defined in terms of addition and negation

Define $rng[t]$ to be the set of all rings in t .

$$rng[t] == \{ Rng[t] \bullet \mathbf{A} \}$$

Example. *The integers with addition and multiplication is a ring.*

$$(\mathbb{Z}, (- + -), (- * -)) \in rng[\mathbb{Z}]$$

1.1.2. *Ring Homomorphisms.* Let \mathbf{A} and \mathbf{A}' be rings. A *ring homomorphism* from \mathbf{A} to \mathbf{A}' is a function f from A to A' that preserves the addition and multiplication operations. As a structure, we represent a ring homomorphism F as the pair $(\mathbf{A}, \mathbf{A}') \mapsto f$.

$$\begin{array}{l}
 \text{Rng_Hom}[\mathbf{t}, \mathbf{u}] \text{ -----} \\
 \text{Rng}[\mathbf{t}] \\
 \text{Rng}'[\mathbf{u}] \\
 f : \mathbf{t} \rightarrow \mathbf{u} \\
 F : (\text{rng}[\mathbf{t}] \times \text{rng}[\mathbf{u}]) \times (\mathbf{t} \rightarrow \mathbf{u}) \\
 \hline
 f \in A \rightarrow A' \\
 \forall x, y : A \bullet f(x + y) = f(x) + f(y) \\
 \forall x, y : A \bullet f(x * y) = f(x) * f(y) \\
 F = (\mathbf{A}, \mathbf{A}') \mapsto f
 \end{array}$$

- f maps A to A'
- f preserves addition
- f preserves multiplication
- the homomorphism as a structure consists of the pair of rings and the map between them

Define $\text{rng_Hom}[\mathbf{t}, \mathbf{u}]$ to be the set of all ring homomorphisms from rings in \mathbf{t} to rings in \mathbf{u} .

$$\text{rng_Hom}[\mathbf{t}, \mathbf{u}] == \{ \text{Rng_Hom}[\mathbf{t}, \mathbf{u}] \bullet F \}$$

Define $\text{rng_hom}(\mathbf{A}, \mathbf{A}')$ to be the set of all ring homomorphism from \mathbf{A} to \mathbf{A}' .

$$\begin{array}{l}
 \text{rng_hom}[\mathbf{t}, \mathbf{u}] == \\
 (\lambda \mathbf{A} : \text{rng}[\mathbf{t}]; \mathbf{A}' : \text{rng}[\mathbf{u}] \bullet \\
 \{ (\mathbf{A}, \mathbf{A}') \} \triangleleft \text{rng_Hom}[\mathbf{t}, \mathbf{u}])
 \end{array}$$

1.1.3. *Identity Maps.* Define $\text{rng_id}[\mathbf{t}]$ to be the function that maps rings in \mathbf{t} to their identity maps.

$$\text{rng_id}[\mathbf{t}] == \{ \text{Rng}[\mathbf{t}] \bullet \mathbf{A} \mapsto ((\mathbf{A}, \mathbf{A}) \mapsto \text{id } A) \}$$

Remark. *The identity map on any ring is a homomorphism.*

$$\text{rng_id}[\mathbf{T}] \in \text{rng}[\mathbf{T}] \rightarrow \text{rng_Hom}[\mathbf{T}, \mathbf{T}]$$

1.1.4. *Composition.* Given ring homomorphisms f from A to A' and f' from A' to A'' , we can define their *composition* $g = f' \circ f$ from A to A'' .

$Rng_Composition[t, u, v]$ $Rng_Hom[t, u]$ $Rng_Hom'[u, v]$ $g : t \rightarrowtail v$ $G : (rng[t] \times rng[v]) \times (t \rightarrowtail v)$	
$g = f' \circ f$ $G = (A, A'') \mapsto g$	

Remark. The composition of ring homomorphisms is a ring homomorphism.

$$\forall Rng_Composition[T, U, V] \bullet G \in rng_hom(A, A'')$$

Let $G = F' \circ F$ denote the composition of ring homomorphisms.

$$(- \circ -)[t, u, v] == \{ Rng_Composition[t, u, v] \bullet (F', F) \mapsto G \}$$

Remark. The identity map is a left and right identity element under composition of ring homomorphisms.

$$\forall Rng_Hom[T, U] \bullet \\ F \circ rng_id(A) = F = rng_id(A') \circ F$$

The preceding remark states that the diagram in Figure 1 commutes.

$$\begin{array}{ccc} A & \xrightarrow{F} & A' \\ \downarrow id & \searrow F & \downarrow id \\ A & \xrightarrow{F} & A' \end{array}$$

FIGURE 1. Composition with the identity homomorphism

1.1.5. *Commutative Rings.* A ring is said to be *commutative* if its multiplication is commutative.

$CommRng[t]$ $Rng[t]$	
$\forall x, y : A \bullet x * y = y * x$	

- multiplication is commutative

Define $commrng[t]$ to be the set of all commutative rings in t .

$$commrng[t] == \{ CommRng[t] \bullet A \}$$

Remark. A commutative ring in t is a ring in t .

$$commrng[T] \subseteq rng[T]$$

A homomorphism of commutative rings is simply a homomorphism of the underlying rings.

$$\begin{array}{l} \text{CommRng_Hom}[\mathbf{t}, \mathbf{u}] \text{ -----} \\ \text{CommRng}[\mathbf{t}] \\ \text{CommRng}'[\mathbf{u}] \\ \text{Rng_Hom}[\mathbf{t}, \mathbf{u}] \end{array}$$

Define $\text{commrng_Hom}[\mathbf{t}, \mathbf{u}]$ to be the set all homomorphisms of commutative rings in \mathbf{t} to commutative rings in \mathbf{u} .

$$\text{commrng_Hom}[\mathbf{t}, \mathbf{u}] == \{ \text{CommRng_Hom}[\mathbf{t}, \mathbf{u}] \bullet F \}$$

Remark. *A homomorphism of commutative rings is a homomorphism of rings.*

$$\text{commrng_Hom}[\mathbf{T}, \mathbf{U}] \subseteq \text{rng_Hom}[\mathbf{T}, \mathbf{U}]$$

Define $\text{commrng_hom}(\mathbf{A}, \mathbf{A}')$ to be the set all homomorphisms from the commutative ring \mathbf{A} to the commutative ring \mathbf{A}' .

$$\begin{array}{l} \text{commrng_hom}[\mathbf{t}, \mathbf{u}] == \\ (\lambda \mathbf{A} : \text{commrng}[\mathbf{t}]; \mathbf{A}' : \text{commrng}[\mathbf{u}] \bullet \\ \{ (\mathbf{A}, \mathbf{A}') \} \triangleleft \text{commrng_Hom}[\mathbf{t}, \mathbf{u}]) \end{array}$$

Define $\text{commrng_id}[\mathbf{t}]$ to be the function that maps commutative rings in \mathbf{t} to their identity maps.

$$\text{commrng_id}[\mathbf{t}] == \{ \text{CommRng}[\mathbf{t}] \bullet \mathbf{A} \mapsto ((\mathbf{A}, \mathbf{A}) \mapsto \text{id } A) \}$$

Remark. *The identity map of a commutative ring is a commutative ring homomorphism from the ring to itself.*

$$\forall \mathbf{A} : \text{commrng}[\mathbf{T}] \bullet \text{commrng_id}(\mathbf{A}) \in \text{commrng_hom}(\mathbf{A}, \mathbf{A})$$

Given commutative ring homomorphisms f from A to A' and f' from A' to A'' , we can define their *composition* $g = f' \circ f$ from A to A'' .

$$\begin{array}{l} \text{CommRng_Composition}[\mathbf{t}, \mathbf{u}, \mathbf{v}] \text{ -----} \\ \text{CommRng_Hom}[\mathbf{t}, \mathbf{u}] \\ \text{CommRng_Hom}'[\mathbf{u}, \mathbf{v}] \\ g : \mathbf{t} \rightarrow \mathbf{v} \\ G : (\text{commrng}[\mathbf{t}] \times \text{commrng}[\mathbf{v}]) \times (\mathbf{t} \rightarrow \mathbf{v}) \\ \hline g = f' \circ f \\ G = (\mathbf{A}, \mathbf{A}'') \mapsto g \end{array}$$

Remark. *The composition of commutative ring homomorphisms is a commutative ring homomorphism.*

$$\forall \text{CommRng_Composition}[\mathbf{T}, \mathbf{U}, \mathbf{V}] \bullet G \in \text{commrng_hom}(\mathbf{A}, \mathbf{A}'')$$

Let $G = F' \circ F$ denote the composition of commutative ring homomorphisms.

$$(- \circ -)[\mathbf{t}, \mathbf{u}, \mathbf{v}] == \{ \text{CommRng_Composition}[\mathbf{t}, \mathbf{u}, \mathbf{v}] \bullet (F', F) \mapsto G \}$$

TODO: define homomorphisms, identity maps, composition, and composition with identity maps

1.1.6. *Unital Rings.* A ring is said to have an *identity element* if it has a left and right multiplicative identity element. In other words, the multiplication operation is a monoid. A ring with an identity element is also said to be a *unital* ring. The multiplicative identity element of a unital ring is denoted 1.

$\text{Ring}[\mathbf{t}]$	_____
$\text{Rng}[\mathbf{t}]$	
$1 : \mathbf{t}$	
$(A, (- * -)) \in \text{monoid}[A]$	
$1 = \text{identity_element}(A, (- * -))$	

- the multiplication operation is a monoid
- the multiplicative identity element is denoted 1

Define $\text{ring}[\mathbf{t}]$ to be the set of all unital rings in \mathbf{t} .

$$\text{ring}[\mathbf{t}] == \{ \text{Ring}[\mathbf{t}] \bullet \mathbf{A} \}$$

TODO: define homomorphisms, identity maps, composition, and composition with identity maps

1.1.7. *Commutative Unital Rings.* Commutative algebra is primarily concerned with commutative, unital rings.

$\text{CommRing}[\mathbf{t}]$	_____
$\text{Ring}[\mathbf{t}]$	
$\text{CommRng}[\mathbf{t}]$	

Define $\text{commring}[\mathbf{t}]$ to be the set of commutative unital rings in \mathbf{t} .

$$\text{commring}[\mathbf{t}] == \{ \text{CommRing}[\mathbf{t}] \bullet \mathbf{A} \}$$

TODO: define homomorphisms, identity maps, composition, and composition with identity maps

For the remainder of this article the term *ring* will mean a commutative unital ring. However, the formal notation will always be explicit.

1.1.8. *Zero Rings.* If the additive and multiplicative identity elements are the same then the ring is said to be a *zero ring*.

$\text{ZeroRing}[\mathbf{t}]$	_____
$\text{Ring}[\mathbf{t}]$	
$1 = 0$	

- the additive and multiplicative identity elements are the same

Remark. *A zero ring contains exactly one element, namely the zero element.*

$$\forall \text{ZeroRing}[\mathsf{T}] \bullet A = \{0\}$$

Proof.

$$\begin{array}{ll} x : A & [\text{assumption-intro}] \\ x & \\ = x * 1 & [1 \text{ is the identity element}] \\ = x * 0 & [1 = 0 \text{ by } \text{ZeroRing}] \\ = 0 & [0 \text{ is the zero element}] \\ x : A \Rightarrow x = 0 & [\text{assumption-elim}] \\ A = \{0\} & [\text{set extensionality}] \end{array}$$

□

TODO: remark on the universal properties of the zero ring in each of the four categories of rings

1.1.9. *Ring Homomorphisms.* A homomorphism of commutative unital rings is a mapping f from ring A into ring A' that preserves addition, multiplication, and identity elements.

$\begin{array}{l} \text{CommRing_Hom}[\mathsf{t}, \mathsf{u}] \\ \text{CommRing}[\mathsf{t}] \\ \text{CommRing}'[\mathsf{u}] \\ \text{Rng_Hom}[\mathsf{t}, \mathsf{u}] \\ f : \mathsf{t} \rightarrow \mathsf{u} \end{array}$	$\begin{array}{l} f \in A \rightarrow A' \\ \forall x, y : A \bullet f(x + y) = f(x) + f(y) \\ \forall x, y : A \bullet f(x * y) = f(x) * f(y) \\ f(1) = 1' \end{array}$
--	--

TODO: merge this in with the general discussion of homomorphisms

1.1.10. *Subrings.* A subring A of A' is a subset of elements that contains the identity element and is closed under addition and multiplication.

TODO: use S and A to match textbook

$CommRing_Subring[t]$ $CommRing'[t]$ $A : \mathbb{P} t$	_____
$A \subseteq A'$ $1' \in A$ $\forall x, y : A \bullet x +' y \in A$ $\forall x, y : A \bullet x *' y \in A$	

A subring itself becomes a ring by restriction of the enclosing ring operations.

$CommRing_Restriction[t]$ $CommRing_Subring[t]$ $CommRing[t]$	_____
$(- + -) = (\lambda x, y : A \bullet x +' y)$ $(- * -) = (\lambda x, y : A \bullet x *' y)$	

Set inclusion defines a map f from the subring to the ring.

$CommRing_Inclusion[t]$ $CommRing_Restriction[t]$ $f : t \rightarrow t$ $F : (commring[t] \times commring[t]) \times (t \rightarrow t)$	_____
$f = id A$ $F = (A, A') \mapsto f$	

Remark. *Subring inclusion is a ring homomorphism.*

$\forall CommRing_Inclusion[T] \bullet CommRing_Hom[T, T]$

1.1.11. *Composition.* Given homomorphisms $f : A \rightarrow A'$ and $f' : A' \rightarrow A''$ their composition $f' \circ f$ is a mapping $g : A \rightarrow A''$.

$CommRing_Composition[t, u, v]$ $CommRing_Hom[t, u]$ $CommRing_Hom'[u, v]$ $g : t \rightarrow v$	_____
$g = f' \circ f$	

Remark. *The composition of homomorphisms is a homomorphism.*

TODO: merge with general discussion

NOTE: the preceding sections should be completed and made consistent with each other, however, I will continue on with formalizing the content of Atiyah-MacDonald so I can determine if anything is actually hard to formalize, and also so that I can be more effective with Macaulay 2.

1.2. Ideals. Quotient rings. An *ideal* \mathfrak{a} of a ring A is a subset of A that is an additive subgroup and is such that $A\mathfrak{a} \subseteq \mathfrak{a}$.

$Ideal[t]$ $CommRing[t]$ $\mathfrak{a} : \mathbb{P} t$
$\mathfrak{a} \subseteq A$ $\forall x, y : \mathfrak{a} \bullet x + y \in \mathfrak{a} \wedge x - y \in \mathfrak{a}$ $\forall x : A; y : \mathfrak{a} \bullet x * y \in \mathfrak{a}$

- the ideal is a subset of the ring
- the ideal is closed under addition and subtraction, making it a subgroup
- the ideal is closed under multiplication by elements of the ring

The quotient group A/\mathfrak{a} inherits a well-defined multiplication from A making it a ring called the *quotient ring* (or *residue class ring* A/\mathfrak{a}).

$QuotientRing[t]$ $CommRing_Hom[t, \mathbb{P} t]$ $Ideal[t]$
$f = (\lambda x : A \bullet \{ y : \mathfrak{a} \bullet x + y \})$ $A' = \text{ran } f$

TODO: first define the quotient group and the projection and cosets, showing that the projection is a homomorphism. we need to show that the cosets form an additive group. Then show that the cosets form a monoid. The moral of the story is that I can't skip any steps. Otherwise the definitions get big and repetitive.

1.3. Zero-divisors. Nilpotent elements. Units.

1.4. Prime ideals and maximal ideals.

1.5. Nilradical and Jacobson radical.

1.6. Operations on ideals.

1.7. Extension and contraction.

1.8. Exercises.
